

Return Type in Method

A return type specifies the type of value that a method sends back to the caller after execution. If a method returns a value, the return type must match the type of that value. If a method does not return any value, we use void as the return type.

Syntax

```
Access-modifier modifier return-Type methodName()  
{  
    // code  
    return value;  
}
```

Example

```
public static int addition(int a, int b)  
{  
    int sum = a + b;  
    return sum;  
}
```

Here :

int

The method will return an integer value.

return sum;

Returns the value of sum to the method caller.

Example

void Return Type

```
public static void message()  
{  
    System.out.println("Welcome to Java");  
}
```

Here

- void means the method does not return anything.
- It only performs a task.

Output

Welcome to Java

Return Type	Returns value
int	Integer value
double	Decimal value

char	Single character
String	Text value
boolean	true or false
void	Nothing

Key Point

- A return type defines what value a method sends back after execution.
- Use return statement to send a value back.
- The returned value must match the method's return type.
- Use void when no value needs to be returned.
